

ASTRAJAX

AI that actually gets used

For the people closest to the work.

What it is

AstraJax is an AI command centre for founders, commercial leaders, and function experts — the people who know the work best. It helps them shape clean context, governed agent fleets, prompts, approvals, and AI habits their teams can actually trust.

How it works

Clive thinks with you. Pam challenges the plan. You decide. Doc executes — with a paper trail.

Why it sticks

The system adapts to the human before the human adapts to the system.

Built by operators, for operators.

Proven in production at Butternut Box

Matthew led & grew a 20 person sales function at a start up to a **120 strong sales force** within a **unicorn** in 6 years. Advocating for a **decentralised AI-champion** approach with domain experts as system architects, he **solo built** an **£8m / year** operating system from scratch. First came the data layer, then 600 **React / TypeScript** files for the interfaces and finally **14 production grade agents** on top of it all.

AstraJax productises that journey and gives non-technical users the tools & knowledge that he wishes he had at the start. It creates a safe environment for non-technical users to drive AI adoption and deploy tightly scoped agents on top of clean data.

Never handwritten a line of code – built with AI on clean data

From heroic effort to repeatable systems.

01 Agents absorbed the admin.

A real sales team moved copy-paste, chasing and reconciliation into a fleet of narrow agents working on clean, centralised data.

02 One job, one clean handoff.

Link, propose, human approves, execute — every change logged with a full audit trail.

03 People rose to judgement.

Leaders gained reliable visibility; high-value people moved from admin toward coaching, decisions and improving the system.

04 Story made adoption stick.

Characterful agents turned abstract automation into roles people could understand, remember and trust — human enough to use, without removing human judgement.

05 The system kept improving.

The team reported issues in plain language; Doc shaped them into fix packages, Matthew approved, Cursor implemented, and reporters signed off. No developer queue required.

international markets adopted

Context bloat and poor context maintenance is the **silent killer** of AI adoption.

A flood of context is coming — users are engaging more, and the tools are becoming more powerful.

The dam needs to be built by **the people closest to the work** — not by central technical functions acting as middlemen.

Building is commoditised – adoption is the **moat**
